

## 1 – Endothermic and Exothermic Reactions

<b>Conservation of Energy</b>	Energy is <b>conserved</b> in chemical <b>reactions</b> . The amount of <b>energy</b> in the <b>universe</b> at the <b>end</b> of a chemical reaction is the <b>same</b> as <b>before</b> it takes place.
<b>Exothermic reaction</b>	A reaction which <b>transfers energy</b> to the <b>surroundings</b> . It causes <b>increase in temperature</b> of surroundings.
<b>Examples</b>	<b>Combustion, neutralisation, oxidation and respiration.</b> Everyday uses include <b>hand warmers</b> and <b>self-heating cans</b> .
<b>Endothermic reactions</b>	A reaction where <b>energy is taken in</b> from the <b>surroundings</b> . It causes a <b>decrease in temperature</b> of the surroundings.
<b>Examples</b>	<b>Thermal decomposition</b> and <b>photosynthesis</b> . Everyday uses include <b>sports injury packs</b> .

## 2 – Reaction profiles

<b>Exothermic reactions</b>	 <p>-Energy level <b>decreases</b> because energy is <b>given out</b> to <b>surroundings</b>. -<b>Products</b> are at a <b>lower energy</b> than the <b>reactants</b>. -The <b>difference in height</b> represents the <b>overall energy change</b>. -<b>Initial rise</b> represents the <b>activation energy</b>.</p>
<b>Endothermic reactions</b>	 <p>-Energy level <b>increases</b> because energy is <b>taken in</b> from the <b>surroundings</b>. -<b>Products</b> are at a <b>higher energy</b> than the <b>reactants</b>. -The <b>difference in height</b> represents the <b>overall energy change</b>. -<b>Initial rise</b> represents the <b>activation energy</b>.</p>
<b>Activation energy</b>	The <b>minimum</b> amount of <b>energy</b> that <b>particles</b> must have to <b>react</b> .

## 3 – Temperature changes

<b>Equipment</b>	 <p>-<b>Polystyrene cup and cotton wool for insulation</b> to prevent energy loss. -<b>Lid</b> to reduce energy loss by <b>evaporation</b>.</p>
<b>Variables</b>	This equipment could be used to investigate effect of <b>concentration, mass or volume</b> of reactants on <b>temperature change</b> .

## 4 – Bond energies (HT)

<b>Bond breaking</b>	<b>Bond breaking</b> is <b>endothermic</b> as <b>energy</b> must be <b>supplied</b> to <b>break bonds</b> .
<b>Bond forming</b>	<b>Bond forming</b> is <b>exothermic</b> as <b>energy</b> is <b>released</b> when <b>new bonds</b> are <b>formed</b> .
<b>Bond energy example calculation</b>	<p>Using the <b>bond energies</b> given, calculate the <b>energy change</b> for the reaction between <math>H_2</math> and <math>Cl_2</math> forming <math>HCl</math>:</p> $H-H + Cl-Cl \rightarrow H-Cl \quad H-H: +436 \text{ kJ/mol} \quad Cl-Cl: +242 \text{ kJ/mol}$ $H-Cl \quad H-Cl: +431 \text{ kJ/mol}$ <ol style="list-style-type: none"> <li><b>Find the energy required to break the original bonds:</b> <math>(1 \times H-H) + (1 \times Cl-Cl) = 436 + 242 = 678 \text{ kJ/mol}</math></li> <li><b>Find the energy released by forming the new bonds:</b> <math>2 \times H-Cl = 2 \times 431 \text{ kJ/mol} = 862 \text{ kJ/mol}</math></li> <li><b>Find the overall energy change for the reaction:</b> <b>Overall energy change = breaking bonds – forming bonds</b> <math>678 \text{ kJ/mol} - 862 = -184 \text{ kJ/mol}</math></li> </ol>
